Signals

## Signals

- A **signal** is a representation of the behavior or attributes of some phenomenon.
- A signal is represented mathematically by a function:
- Let  $T$  be the set of possible times, and  $t \in T$  be the time.
- Then, a signal  $f$  can be represented by function  $f : T \rightarrow \vartheta$ , so  $f(t) \in \vartheta$  represents the value of the signal at time  $t \in T$ .
  - The independent variable is the time.
  - The dependent variables is the variable representing some attribute of the phenomenon, it is usually a **physical variable**.

Notes

---

---

---

---

---

---

---

## Signals

Signals can be represented as any mathematical function by:

- a data table specifying the value of the signal or each time value or,
- a mathematical expression that allows to calculate the value of the signal or each time value or,
- a plot showing the value of the signal for each time value.

## Classification of signals

- Depending on the continuous or discrete nature of the sets  $T$  and  $\vartheta$ , the signals can be classified as:
  - **Discrete time signals** when  $T$  is a discrete set.
  - **Continuous time signals** when  $T$  is a continuous set.
  - **Discrete variable signals** when  $\vartheta$  is a discrete set.
  - **Continuous variable signals** when  $\vartheta$  is continuous set.
  - A signal is **digital** when it is discrete time and discrete variable.
  - A signal is **analog** when it is continuous time and continuous variable.

**Note:**

- A continuous set is a set for which there exists a bijective function with the real set,  $\mathbb{R}$ .
- A discrete set is a set for which there exists a bijective function with a nonempty subset of the integers set,  $\mathbb{Z}$ .

## Classification of signals

- A signal is a **deterministic signal** if the signal is known with complete certainty.
- A signal is a **random signal** or **stochastic signal** if there is uncertainty in any feature of the signal.
- A signal  $x(t)$  is **periodic** if there exists  $T > 0$  such that  $x(t) = x(t + T)$  for all  $t \in \mathbb{R}$ . Otherwise the signal is **aperiodic**.

---

---

---

---

---

---

---

## Some simple signals: the singular signals

- Unit step signal:

$$1(t) = \begin{cases} 0, & t < 0 \\ 1, & t \geq 0 \end{cases}$$

### Notes

---

---

---

---

---

---

---

---

## Some simple signals: the singular signals

- Unit ramp signal:

$$r(t) = \begin{cases} 0, & t < 0 \\ t, & t \geq 0 \end{cases}$$

Notes

---

---

---

---

---

---

---

---

## Some simple signals: the singular signals

- Unit parabola signal:

$$p(t) = \begin{cases} 0, & t < 0 \\ \frac{t^2}{2}, & t \geq 0 \end{cases}$$

Notes

---

---

---

---

---

---

---

---

## Some simple signals

- Sinusoidal signal.

$$x(t) = A \cos(\omega t + \phi)$$

Notes

---

---

---

---

---

---

---

---

## Sinusoidal signal parameters

- Sinusoidal signal.

$$x(t) = A \cos(\omega t + \phi)$$

A: amplitude

$\omega$ : angular frequency [=]rad/s

$\phi$ : phase [=]rad

$f = \frac{\omega}{2\pi}$ : frequency [=]Hz = s<sup>-1</sup>

$T = \frac{1}{f} = \frac{2\pi}{\omega}$ : period [=]s

Notes

---

---

---

---

---

---

---

---

## Operations with signals

- Addition/subtraction.
- Differentiation.
- Integration.

Notes

---

---

---

---

---

---

---

---

## Representation of some signals in terms of singular signals

### Example

Plot the signals

- $f(t) = 1(t+3) + r(t+2) - 2r(t) + r(t-2) - 1(t-3)$
- The **rectangular or unit pulse signal**:  
 $\Pi(t) = 1(t+1/2) - 1(t-1/2)$
- The **triangle signal**:  $\Lambda(t) = r(t+1) - 2r(t) + r(t-1)$

Represent the signal  $x(t)$  in terms of singular signals

## Systems

- A **system** is a set of interacting or interdependent components forming an integrated whole for a common purpose.
- A **subsystem** is a system that is part of another system.
- Signals are used for the variables that represent the behavior of the system.
- The system interacts with the environment through input and output signals.
- **Input signals** represent interactions from the environment acting on the system.
- **Output signals** represent interactions from the system acting on the environment.
- **Internal signals** represent interactions among internal components of the system.

Notes

---

---

---

---

---

---

---

---

## Mathematical models

- A system can be represented by a **mathematical model**.
- A mathematical model is a mathematical representation of the system through a set of relations among the signals that represent the physical variables involved in the system.
- In the mathematical model also appear some **parameters** representing the properties or attributes of the components of the system.
- The solutions of the mathematical model approximate the behavior of the system.
- A system can be represented by many mathematical models with different levels of approximation of the system behavior. That's why there is no unique mathematical model for a system.

Notes

---

---

---

---

---

---

---

---

## Mathematical model abstraction

- A system can be abstracted mathematically as an operator that maps the input signals into the output signals.
- That is:

$$y(t) = \mathcal{H}\{u(t)\}$$

where  $u(t)$  is the input signal and  $y(t)$  is the output signal.

- Graphically:

Notes

---

---

---

---

---

---

## Classification of Mathematical models

- According to the number of inputs/outputs:
  - Single Input Single Output (SISO) systems.  
One input/one output.
  - Multiple Input Multiple Output (MIMO) systems.  
Several inputs and/or several outputs.
- According to the time:
  - Continuous time systems.  
System signals are continuous time.
  - Discrete time systems.  
System signals are discrete time.
- According to the dependent variable:
  - Continuous variable systems.  
System signals are continuous variable signals.
  - Discrete variable systems.  
System signals are discrete variable signals.

Notes

---

---

---

---

---

---

---

---

## Classification of Mathematical models

- According to the determinism:
  - Deterministic systems.  
There is no uncertainty in system behavior.
  - Stochastic systems.  
There is uncertainty in system behavior.
- According to the distribution in space:
  - Lumped parameter systems.  
Position in the system is not relevant for the signals.  
Signals only depend on time.
  - Distributed parameter systems.  
Position in the system is not relevant for the signals.  
Signals are dependent on time and position.

Notes

---

---

---

---

---

---

---

## Classification of Mathematical models

- According to the dynamism:
  - Instantaneous systems.  
A system is instantaneous if  $y(t_0) = \mathcal{H}\{u(t_0)\}$  for all  $t_0 \in \mathbb{R}$ .  
That is, a system is instantaneous if  $y(t_0)$  only depends on  $u(t_0)$  for any input signal.
  - Dynamic systems.  
A system is dynamic if  $y(t_0) = \mathcal{H}\{u(t)\}$  for some  $t \neq t_0$ , for some  $t_0 \in \mathbb{R}$ .  
That is, a system is dynamic if  $y(t_0)$  may depend on  $u(t)$  for some  $t \neq t_0$ .

Notes

---

---

---

---

---

---

---

---

## Classification of Mathematical models

- According to the causality:
  - Causal systems.  
For a system such that  $y_1(t) = \mathcal{H}\{u_1(t)\}$  and  $y_2(t) = \mathcal{H}\{u_2(t)\}$ , the system is causal if  $y_1(t_0) = y_2(t_0)$  implies that  $u_1(t) = u_2(t)$  for  $t \leq t_0$ .  
That is, a system is causal if the output a time  $t_0$ ,  $y(t_0)$ , depends only on values of  $u(t)$  for  $t \leq t_0$  for all  $t_0 \in \mathbb{R}$ .
  - Non causal systems.  
A system is non causal if the output a time  $t_0$ ,  $y(t_0)$ , may depend on values of  $u(t)$  for some  $t > t_0$  for some  $t_0 \in \mathbb{R}$ .

Notes

---

---

---

---

---

---

---

---

## Classification of Mathematical models

- According to the variability in time:
  - Time invariant systems.  
A system is said to be time invariant if  $y(t) = \mathcal{H}\{u(t)\}$  implies that  $y(t - t_0) = \mathcal{H}\{u(t - t_0)\}$  for all  $u(t)$  and for all  $t_0 \in \mathbb{R}$ .
  - Time variable systems.  
A system is said to be time variable if it is not a time invariant system.

Notes

---

---

---

---

---

---

---

---

## Classification of Mathematical models

- According to the linearity:
  - Linear systems.  
A system is said to be linear if given that  $y_1(t) = \mathcal{H}\{u_1(t)\}$  and  $y_2(t) = \mathcal{H}\{u_2(t)\}$ , that implies that  $\mathcal{H}\{a_1 u_1(t) + a_2 u_2(t)\} = a_1 \mathcal{H}\{u_1(t)\} + a_2 \mathcal{H}\{u_2(t)\} = a_1 y_1(t) + a_2 y_2(t)$  for any  $a_1, a_2 \in \mathbb{R}$ , and any  $u_1(t), u_2(t)$ .
  - Nonlinear systems.  
A system is said to be nonlinear if it is not a linear system.
